PRODUCT MONOGRAPH

EUFLEX*

(flutamide 250 mg tablets)

Non-Steroidal Antiandrogen

Merck Canada Inc.
16750 route Transcanadienne
Kirkland, Quebec H9H 4M7

Date of preparation: January 31, 2011

Date of Revision:

Control #: 144560

*Registered Trade Mark
PRODUCT MONOGRAPH

EUFLEX
(flutamide 250 mg tablets)

THERAPEUTIC CLASSIFICATION
Non-steroidal antiandrogen

ACTION and CLINICAL PHARMACOLOGY

Flutamide demonstrates potent antiandrogenic effects by inhibiting androgen uptake and/or inhibiting nuclear binding of androgen in target tissues. In adult male rats, ventral prostate weights and seminal vesicle weights were markedly reduced by daily administration of flutamide.

Pharmacokinetics
Analysis of plasma, urine, and feces following a single oral 200 mg dose of tritium-labelled flutamide to human volunteers showed that the drug is rapidly and completely absorbed. It is excreted mainly in the urine with 4.2% of the dose excreted in the faeces over 72 hours. The composition of plasma radioactivity showed that flutamide is rapidly and extensively metabolized, with flutamide comprising 2.5% of plasma radioactivity one hour after administration. At least six metabolites have been identified in plasma. The major plasma metabolite is a biologically active alpha-hydroxylated derivative, which accounts for 23% of the plasma tritium one hour after drug administration. The major urinary metabolite is 2-amino-5-nitro-4-(trifluoromethyl)phenol.

Following a single 250 mg oral dose to normal adult volunteers, low plasma levels of varying amounts of flutamide were detected. The biologically active alpha-hydroxylated metabolite reaches maximum plasma levels in about two hours, indicating that it is rapidly formed from flutamide. The plasma half-life for this metabolite is about 6 hours.

Following multiple oral dosing of 250 mg three times a day in normal geriatric volunteers, flutamide and its active metabolite approached steady-state plasma levels (based on pharmacokinetic simulations) after the fourth flutamide dose. The half-life of the active metabolite in geriatric volunteers after a single flutamide dose is about 8 hours and at steady-state is 9.6 hours.

Flutamide, in vivo, at steady-state plasma concentrations of 24 to 78 ng/mL is 94% to 96% bound to plasma proteins. The active metabolite of flutamide, in vivo, at steady-state plasma concentrations of 1556 to 2284 ng/mL, is 92% to 94% bound to plasma proteins.
In male rats neither flutamide nor any of its metabolites are preferentially accumulated in any tissue except the prostate after an oral 5 mg/kg dose of $^{14}$C-flutamide. Total drug levels were highest 6 hours after drug administration in all tissues. Levels declined at roughly similar rates to low levels at 18 hours. The major metabolite was present at higher concentrations than flutamide in all tissues studied.

Elevations of plasma testosterone and estradiol levels have been noted following flutamide administration.

**INDICATIONS AND CLINICAL USE**

**EUFLEX** (flutamide) Tablets are indicated for use in combination with LHRH agonistic analogues (such as leuprolide acetate) for the treatment of metastatic prostatic carcinoma (stage D$_2$). To achieve the benefit of the adjunctive therapy with **EUFLEX**, treatment must be started simultaneously using both drugs. **EUFLEX** Tablets are also indicated as an adjunctive therapy to orchiectomy, in order to achieve complete androgen blockade.

**EUFLEX** Tablets in combination with LHRH agonists are also indicated prior to and during definitive external beam radiotherapy for patients with bulky locally advanced Stage B$_2$ and Stage C prostatic carcinoma. (See Dosage and Administration).

**CONTRAINDICATIONS**

**EUFLEX** (flutamide) Tablets are contraindicated in patients who have shown hypersensitivity to flutamide or any component of this preparation.

**EUFLEX** is contraindicated in patients with severe hepatic impairment.

**EUFLEX** has not been studied in women and is not indicated for this population, particularly for nonserious or nontreatable conditions.

**WARNINGS**

**General**
- Gynecomastia occurred in 9% of patients receiving flutamide together with medical castration.
- Physicians must familiarize themselves with the proper use of LHRH before combination medication is contemplated.
**Hepatic Injury**
There have been postmarketing reports of hospitalization and rarely death due to liver failure in patients taking flutamide. Evidence of hepatic injury included elevated serum transaminase levels, jaundice, hepatic encephalopathy, and death related to acute hepatic failure. The hepatic injury was reversible after prompt discontinuation of therapy in some patients. Approximately half of the reported cases occurred within the initial 3 months of treatment with flutamide.

Serum transaminase levels should be measured prior to starting treatment with flutamide. Flutamide is not recommended in patients whose ALT values exceed twice the upper limit of normal. Serum transaminase levels should then be measured monthly for the first 4 months of therapy, and periodically thereafter. Liver function tests also should be obtained at the first signs and symptoms suggestive of liver dysfunction, e.g. nausea, vomiting, abdominal pain, fatigue, anorexia, “flu-like” symptoms, hyperbilirubinuria, jaundice, or right upper quadrant tenderness. If at any time a patient has jaundice, or their ALT rises above 2 times the upper limit of normal, flutamide should be immediately discontinued with close follow-up of liver function tests until resolution.

**Antiandrogen Withdrawal Syndrome**
In some patients with metastatic prostate cancer, antiandrogens (steroidal or non-steroidal), may promote, rather than inhibit, the growth of prostate cancer. A decrease in PSA and/or clinical improvement following the discontinuation of antiandrogens have been reported. It is recommended that patients prescribed an antiandrogen, who have PSA progression, should have the antiandrogen discontinued immediately and be monitored for 6-8 weeks for a withdrawal response prior to any decision to proceed with other prostate cancer therapy.

**Use in Pregnancy and Lactation:** No studies have been conducted in pregnant or lactating women. Therefore, the possibility that EUFLEX may cause fetal harm if administered to a pregnant woman, or may be present in the breast milk of lactating women must be considered.

There was decreased 24-hour survival in the offspring of rats treated with flutamide at doses of 30, 100, or 200 mg/kg/day (approximately 3, 9, and 19 times the human dose) during pregnancy. A slight increase in minor variations in the development of the sternbra and vertebra was seen in fetuses of rats at the two higher doses. Feminization of the males also occurred at the two higher dose levels. There was a decreased survival rate in the offspring of rabbits receiving the highest dose (15 mg/kg/day; equal to 1.4 times the human dose).

**PRECAUTIONS**

Periodic liver function tests and sperm count determinations must be performed in patients on long-term treatment with flutamide.
After long-term administration in rats, flutamide produced testicular interstitial cell adenomas and dose-related increases in mammary gland adenomas or carcinomas. The relevance of these findings to humans is unknown. It should be noted that few cases of malignant breast neoplasms have been reported in male patients receiving **EUFLEX** (flutamide); causality has not been established.

Since flutamide tends to elevate plasma testosterone and estradiol levels, fluid retention may occur. Accordingly, flutamide should be used with caution in those patients with cardiac disease.

**Hepatic Injury**: Treatment with **EUFLEX** should not be initiated in patients with serum transaminase levels exceeding 2 to 3 times the upper limit of normal.

Since transaminase abnormalities, cholestatic jaundice, hepatic necrosis and hepatic encephalopathy have been reported with the use of flutamide, periodic liver function tests must be performed in all patients.

Appropriate laboratory testing should be done monthly for the first 4 months, and periodically thereafter and at the first symptom/sign of liver dysfunction (e.g., pruritus, dark urine, persistent anorexia, jaundice, right upper quadrant tenderness or unexplained "flu-like" symptoms).

If the patient has laboratory evidence of liver injury or jaundice, in the absence of biopsy-confirmed liver metastases, flutamide therapy should be discontinued if the patient develops jaundice or if serum transaminase levels rise to 2 to 3 times the upper limit of normal, even in clinically asymptomatic patients.

The hepatic injury is usually reversible after discontinuation of therapy and in some patients, after dosage reduction. However, there have been reports of death following severe hepatic injury associated with the use of flutamide.

**Drug interactions**: Interactions between **EUFLEX** Tablets and leuprolide have not occurred. In patients receiving long-term oral-anticoagulant therapy, increases in prothrombin time have been reported after flutamide monotherapy was initiated. Therefore close monitoring of prothrombin time is recommended and adjustment of the anticoagulant dose may be necessary when flutamide tablets are administered concomitantly.

Cases of increased theophylline plasma concentrations have been reported in patients receiving concomitant theophylline and flutamide tablets. Theophylline is primarily metabolized by CYP 1A2, which is the primary enzyme responsible for the conversion of flutamide to its active agent 2-hydroxyflutamide.

**Information for Patients**: Patients should be informed prior to initiating this medication, of the possibility of its causing hepatic dysfunction. Instruct the patient to consult the doctor immediately if symptoms of hepatic dysfunction appear. These include itching of the skin, dark urine (amber or yellow-green urine is not a cause of concern), nausea, vomiting,
persistent lack of appetite, yellow eyes or skin, tenderness in the right upper abdomen, or “flu-like” symptoms.

**EUFLEX** (flutamide) is indicated only for use in male patients.

Patients should be informed that **EUFLEX** and the drug used for medical castration should be administered concomitantly, and that they should not interrupt their dosing or stop taking these medications without consulting their physician.

### ADVERSE REACTIONS

The most frequently reported adverse reactions to **EUFLEX** (flutamide) Tablets monotherapy are gynecomastia and/or breast tenderness, sometimes accompanied by galactorrhoea. These reactions disappear upon discontinuation of treatment or reduction in dosage. The incidence of gynecomastia is reduced greatly when **EUFLEX** Tablets are administered concomitantly with an LHRH agonist.

The most frequently reported (greater than 5%) adverse experiences during treatment with **EUFLEX** Tablets in combination with a LHRH agonist are listed in the table below. For comparison, adverse experiences seen with a LHRH agonist and placebo are also listed in the following table.

<table>
<thead>
<tr>
<th></th>
<th>(n=294) Flutamide + LHRH-agonist</th>
<th>(n=285) Placebo + LHRH-agonist</th>

</tbody>
</table>

As shown in the table, for both treatment groups, the most frequently occurring adverse experiences (hot flashes, loss of libido, impotence) were those known to be associated with low serum androgen levels and known to occur with LHRH-agonists alone.

The only notable difference between these treatment groups was the higher incidence of diarrhea in the flutamide + LHRH-agonist group (12%; severe in 5%) as compared to the placebo + LHRH-agonist group (4%; were severe in less than 1%).
In addition, the following adverse reactions were reported during treatment with flutamide +LHRH-agonist. No causal relatedness of these reactions to drug treatment has been made, and some of the adverse experiences reported are those that commonly occur in elderly patients.

**Cardiovascular System:** hypertension in 1% of patients. Rarely thrombophlebitis, pulmonary embolism, myocardial infarction.

**Central Nervous System:** CNS (drowsiness/confusion/depression/anxiety/nervousness) reactions occurred in 1% of patients. Rarely insomnia, tiredness, headache, dizziness, weakness, malaise, blurred vision and decreased libido have been reported.

**Endocrine System:** gynecomastia in 9% of patients. Rarely breast tenderness sometimes accompanied by galactorrhoea.

**Gastrointestinal System:** nausea/vomiting occurred in 11%; diarrhea 12%, anorexia 4%, and other gastro-intestinal disorders occurred in 6% of patients. Increased appetite, indigestion and constipation have also been reported.

**Hematopoietic System:** anaemia occurred in 6% of patients, leukopenia 3%, thrombocytopenia 1%.

**Liver and Biliary System:** clinically evident hepatitis and jaundice occurred in <1% of patients.

**Skin:** irritation at the injection site and rash occurred in 3% of patients. Photosensitivity reactions have been reported in five patients.

**Other:** Pruritus, ecchymosis, herpes zoster, thirst, lymphedema, lupus-like syndrome, hematuria, reduced sperm counts have been reported rarely in long-term treatment. Edema occurred in 4% of patients; neuromuscular, genitourinary symptoms occurred in 2% of patients. Interstitial lung disease occurred in <1% of patients.

**Additional Adverse Experiences:** In addition, the following adverse experiences have been reported during world-wide marketing of EUFLEX Tablets: hemolytic anemia, macrocytic anemia, methemoglobinemia, sulfhemoglobinemia, photosensitivity reactions -- including erythema, ulcerations, bullous eruptions, and epidermal necrolysis -- and change in urine color to an amber or yellow-green appearance, which can be attributed to flutamide and/or its metabolites. Also observed were cholestatic jaundice, hepatic encephalopathy and hepatic necrosis. The hepatic conditions were usually reversible after discontinuing therapy; however, there have been reports of death following severe hepatic injury associated with use of flutamide. Hyperglycemia and aggravated diabetes mellitus have been reported very rarely.

Two reports of malignant male breast neoplasms in patients being dosed with EUFLEX have been reported. One involved aggravation of a pre-existing nodule which was first detected
three to four months before initiation of EUFLEX monotherapy in a patient with benign prostatic hypertrophy. After excision, this was diagnosed as a poorly differentiated ductal carcinoma. The other report involved gynecomastia and a nodule noted two and six months respectively, after initiation of EUFLEX monotherapy for treatment of advanced prostatic carcinoma. Nine months after the initiation of therapy, the nodule was excised and diagnosed as a moderately differentiated invasive ductal tumor staged T4N0M0, G3, no metastases had advanced.

**Laboratory Values:** Reported abnormal laboratory test results include elevated SGOT (AST), SGPT (ALT); elevated blood urea nitrogen (BUN) and bilirubin levels; less frequently, elevated serum creatinine levels and elevated gamma-glutamyl transferase levels have been reported.

**SYMPTOMS AND TREATMENT OF OVERDOSE**

In animal studies with flutamide alone, signs of overdose included hypoactivity, piloerection, slow respiration, ataxia, and/or lacrimation, anorexia, tranquillization, emesis and methemoglobinemia.

Clinical trials have been conducted with flutamide in doses up to 1500 mg per day for periods up to 36 weeks with no serious adverse effects reported. Those adverse reactions reported included gynecomastia, breast tenderness and some increases in SGOT. The single dose of flutamide ordinarily associated with symptoms of overdose or considered to be life-threatening has not been established.

Since flutamide is highly protein bound, dialysis may not be of any use as treatment for overdose. As in the management of overdosage with any drug, it should be borne in mind that multiple agents may have been taken. Gastric lavage may be considered. General supportive care, including frequent monitoring of the vital signs and close observation of the patient, is indicated.

**DOSAGE AND ADMINISTRATION**

The recommended dosage of EUFLEX (flutamide) in combination with orchietomy or in combination with an LHRH agonist is one 250 mg tablet three times a day at eight-hour intervals. In combination with an LHRH agonist, either the two agents may be initiated simultaneously, or EUFLEX tablet therapy may be started 24 hours prior to initiation of the LHRH agonist.

In the management of bulky locally advanced Stage B2 and Stage C prostatic carcinoma, the recommended dosage is one 250 mg tablet, three times a day at eight-hour intervals. EUFLEX should be started simultaneously or 24 hours prior to initiation of the LHRH agonist.
Administration of EUFLEX should begin eight weeks prior to external beam radiation therapy and continue through the course of radiation therapy.
PHARMACEUTICAL INFORMATION

Flutamide:

Molecular Formula: \( \text{C}_{11}\text{H}_{11}\text{N}_{2}\text{O}_{3}\text{F}_{3} \)

Molecular Weight: 276.21

Chemical Name: 2-methyl-N-(4-nitro-3-(trifluoromethyl) phenyl) propanamide.

Description: Buff to yellow powder.

AVAILABILITY OF DOSAGE FORMS

Each round, biconvex, pale yellow, compressed tablet, engraved with "EUFLEX" on one face, and a single score on the other with the "SP" logo engraved on each side of the score line, contains: flutamide 250 mg. Nonmedicinal ingredients: cellulose, lactose, magnesium stearate, pregelatinized starch, silicon dioxide and sodium lauryl sulfate. Tartrazine-free. Bottles of 100. Store between 15° and 30°C. Protect from light and excessive moisture.
- Read this information carefully each time your prescription is refilled because there may be new information available.
- This summary does not tell you everything you need to know about EUFLEX (flutamide) therapy. Your doctor is the best source of information about your treatments. Ask your doctor about questions you have.

**What is EUFLEX Therapy?**

**EUFLEX** tablet, in combination with other therapies, is a treatment option for men with some types of prostate cancer.

Prostate cancer results from the abnormal growth of prostate cells. Medical scientists do not know exactly what causes the abnormal cells, but age, environment and genetics are important factors. Male hormones (“androgens”) cause the cancer to grow. The cancer growth can be slowed down by blocking the effect of androgens.

Prostate-specific antigen (PSA) is a marker used for monitoring cancer progression and response to therapy. PSA can be measured from a blood sample. PSA levels are usually elevated in cancer progression and low when responding to therapy.

**EUFLEX** is used together with an injection called “LHRH agonist”, as a combined treatment, called “total androgen blockade”. The goal of this treatment is to reduce androgen levels and to block the effect of androgen on the tumor. The LHRH agonist reduces androgen levels. **EUFLEX** therapy blocks the effect of androgen on the tumor.

**Who Should Not Take EUFLEX?**

You should not take **EUFLEX** tablets if you have liver problems or if you are allergic to it. Women should not take **EUFLEX** tablets.

**Important Risks You Should Know About EUFLEX Therapy**

Some men taking **EUFLEX** had liver injury and needed to be hospitalized. In rare cases, men died because of liver failure while they were taking **EUFLEX** tablets. In about half of these cases, the liver failure occurred in the first 3 months that they were taking **EUFLEX** tablets.

Because **EUFLEX** can cause liver failure, it is very important that you have all blood tests recommended by your doctor. These tests help identify whether you are having liver problems. A recommended schedule for these blood tests is:
- before starting **EUFLEX** treatment
- every month for the first 4 months of therapy
- periodically after the first 4 months

Also, your doctor will be monitoring your PSA blood concentrations during treatment. If PSA values remain high or start to increase, it is likely that your **EUFLEX** and LHRH agonist treatment will be discontinued. Your PSA values will continue to be monitored for 6 to 8...
weeks after discontinuing treatment to see if the PSA values go down, and whether other forms of treatment should be considered.

In addition, you should call your doctor right away if you have any of the following signs or symptoms:
- loss of appetite
- nausea and vomiting
- stomach or abdominal pain
- fatigue (feeling extremely tired)
- flu-like symptoms (muscle aches, soreness)
- brown urine
- jaundice (yellowing of the skin or whites of the eyes)

**How to Take EUFLEX**
- Take your EUFLEX tablets as your doctor has prescribed.
- Your doctor will determine whether EUFLEX therapy is right for you based on many different factors. These include how large your tumor is, how far it has spread, and your physical condition. In addition to EUFLEX tablets, you may be getting other treatments including regular injections of LHRH agonist or radiation therapy. Do not stop or interrupt any treatment without consulting your healthcare professional.

- If you miss a dose of EUFLEX tablets, simply continue therapy with your next scheduled dose. Do not try to make up for it by taking extra tablets.

**Taking Other Medicines**
If you are taking any other medicines, tell your doctor before beginning EUFLEX therapy. Euflex is known to interact with anti-coagulant medication as well as drugs containing theophylline as an active ingredient.

**Other Possible Side Effects of Taking EUFLEX Tablets**
In a medical study, when EUFLEX tablets were taken together with an LHRH agonist, the most common side effects were hot flashes, loss of sex drive (libido), and impotence. In addition, some men had diarrhea, nausea or vomiting, and breast enlargement.

In another medical study, when EUFLEX was taken together with goserelin acetate (an LHRH agonist) and radiation therapy, the side effects of EUFLEX were about the same as when radiation therapy was given alone. These included hot flashes, diarrhea, nausea, and skin rash.

**What to do when you get Diarrhea**
If you experience moderate diarrhea due to EUFLEX tablets, the following advice may help:
- drink plenty of fluids
- reduce your intake of dairy products (for example, milk, cheese, yogurt)
- increase your intake of whole grains, fruits and vegetables
- stop laxative use
- take nonprescription antidiarrheal medicines
If your diarrhea continues or it becomes severe, contact your doctor right away.

**Other Laboratory Tests Your Doctor May be Performing**
Your doctor may perform other regular tests (such as the PSA [Prostate Specific Antigen] blood test) to ensure that your body is responding to treatment. Ask your doctor if you have any questions about how your **EUFLEX** therapy is being monitored.

Please ask your doctor about any questions concerning prostate cancer or **EUFLEX** therapy, or you can also ask for a more detailed leaflet that is written for healthcare professionals.
PHARMACOLOGY

**General:** In animal studies, flutamide demonstrates potent antiandrogenic effects. It exerts its antiandrogenic action by inhibiting androgen uptake and/or by inhibiting nuclear binding of androgen in target tissues or both. Prostatic carcinoma is known to be androgen-sensitive and responds to treatment that counteracts the effect of androgen and/or removes the source of androgen, e.g. castration.

**CLINICAL STUDIES**

Flutamide has been demonstrated to interfere with testosterone at the cellular level. This can complement medical castration achieved with leuprolide, which suppresses testicular androgen production by inhibiting luteinizing hormone secretion.

**Combination therapy:** To study the effects of combination therapy, 617 patients (311 different leuprolide + flutamide, 306 leuprolide + placebo) with previously untreated advanced prostatic carcinoma were enrolled in a large multicentered, controlled clinical trial.

Three and one-half years after the study was initiated, median survival had been reached. The median actuarial survival times is 34.9 months for patients treated with leuprolide and flutamide versus 27.9 months for patients treated with leuprolide alone. This seven-month increment represents 25% improvement in overall survival with the flutamide therapy. Analysis of progression free survival showed a 2.6 month improvement in patients who received leuprolide plus flutamide, a 19% increment over leuprolide and placebo.

**Locally Advanced Prostatic Carcinoma:** A prospective, multicenter, phase-three trial evaluated the efficacy and safety of the therapy regimen of flutamide and goserelin acetate administered prior to and during definitive external beam radiation therapy to patients with bulky, locally advanced, clinical stage B2 or C prostate cancer. Patients randomized to the treatment group received flutamide at a dose of 750 mg/day (250 mg three times a day) initiated eight weeks prior to the start of radiation therapy and continued for a total of 16 weeks or until the last day of radiation therapy, whichever occurred first. Flutamide treatment was continued during unexpected interruptions of radiation therapy. These patients also received a depot injection of goserelin acetate 3.6 mg administered subcutaneously into the anterior abdominal wall every four weeks for 16 weeks (total 4 injections) beginning eight weeks prior to initiation of radiation therapy. Patients in the control group were treated with radiation only.

The combination of flutamide and goserelin acetate administered prior to and during radiation therapy increased disease-free survival and loco-regional control without a clinically significant increase in toxicity. Approximately 75% of patients in both groups were alive four years after initial randomization; local failure occurred in 33% of the controls, but in only 16% of the treated patients (p<0.001). Over four years, 36% of the controls vs. 27% of the treated patients developed distant metastasis.
When prostate-specific antigen (PSA) levels were not used as a criterion for the presence of disease, duration of disease-free survival was significantly longer in treated patients than in controls (p<0.001). Treated patients had an estimated median disease-free survival time of 4.4 years as compared to 2.6 years for control patients. Similarly, when normal PSA levels were considered as part of the survival criteria, treated patients had a significantly longer median disease-free survival time than controls (p<0.001). Patients in the treated group had an estimated median disease-free survival period of 2.7 years, while control patients achieved an estimated median disease-free survival time of 1.5 years. It is noteworthy that the increase in disease-free survival time observed among treated patients was achieved with 16 weeks of reversible androgen blockade.

External beam radiation therapy morbidity was not increased by the added combination of flutamide and goserelin acetate. Hot flashes and diarrhea were the most commonly reported adverse events among treated patients (46% and 40%, respectively). Diarrhea also was reported in 40% of the control patients as a late effect of the radiation therapy. Gynecomastia was reported in 3% of the treated patients; elevated SGOT levels were observed in 1% of patients in the treated group. Although more treated patients than controls had abnormal SGOT and/or SGPT levels during the follow-up period, more treated than control patients also had abnormal baseline values as well. During the follow-up period, levels of acid phosphatase were higher in controls than in treated patient.

**TOXICOLOGY**

Signs of flutamide overdose were hypoactivity, piloerection, slow respiration, ataxia and/or lacrimation as seen in rat, mouse and guinea pig. Anorexia, tranquillization and emesis were observed in the cat and dog. The oral LD_{50} was in excess of 1000 mg/kg in the cat and dog.

A 52-week chronic oral toxicity study in male and female rats produced a dose-related decrease in body weight gain. Necropsy revealed the following drug-related changes: reduction in prostatic, seminal vesicle and male kidney size; a reduction in testicular or uterine size in the highest dosage groups (18 times human dose); increase in liver size, unusually textured and colored testes, and in females suppression of lactation. Histological drug-related changes in males included testicular interstitial cell hyperplasia, interstitial space edema, and at 52 weeks only, interstitial cell adenoma, spermatogenesis suppression, seminal vesicle and prostatic atrophy and an increase in the number of pituitary castration cells. The adenoma was related to the mechanism of action of flutamide and was species specific.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Daily administration of flutamide to rats for 52 weeks at doses of 30, 90, or 180 mg/kg/day (approximately 3, 8, or 17 times the human dose), produced testicular interstitial cell adenomas at all doses.
Flutamide did not demonstrate DNA modifying activity in the Ames Salmonella/microsome Mutagenesis Assay. Dominant lethal tests in rats were negative.

Reduced sperm counts were observed during a six-week study of flutamide monotherapy in normal volunteers. Flutamide did not affect estrous cycles or interfere with the mating behaviour of male and female rats when the drug was administered at 25 and 75 mg/kg/day prior to mating. Males treated with 150 mg/kg/day (30 times the minimum effective antiandrogenic dose) failed to mate; mating behaviour returned to normal after dosing was stopped. Conception rates were decreased in all dosing groups. Suppression of spermatogenesis was observed in rats dosed for 52 weeks at approximately 3, 8, or 17 times the human dose and in dogs dosed for 78 weeks at 1.4, 2.3, and 3.7 times the human dose.

Histologic changes characteristic of the antiandrogenic activity of flutamide were observed in all species, and there was evidence of suppressed spermatogenesis. In rats only, testicular interstitial cell adenomas were increased in number after chronic administration of flutamide independent of the dose administered. In the chronic toxicity studies in male rats, dose-dependent increases in mammary gland adenomas and carcinomas were observed. Both of these findings are related to the recognized mechanism of action of flutamide on endocrine sensitive cells.
